

A

Mutation frequency in metastatic sites

Non-silent driver mutations, MSK-MET CRC metastatic samples

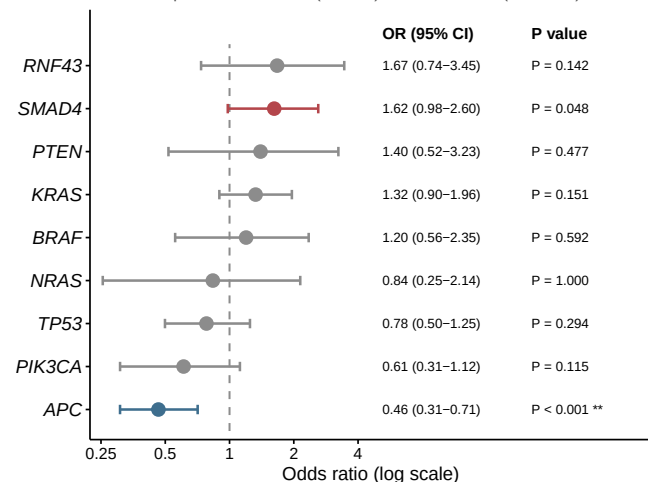

*** FDR < 0.001 (Fisher, peritoneal vs liver, BH).
Peritoneal = intra-abdominal + ovary pooled (n = 124);
Fisher test: same pooled group vs liver (n = 624).

B

Patient-level enrichment, peritoneal involvement

Fisher test: peritoneal-involved (n = 124) vs non-involved (n = 1,023)

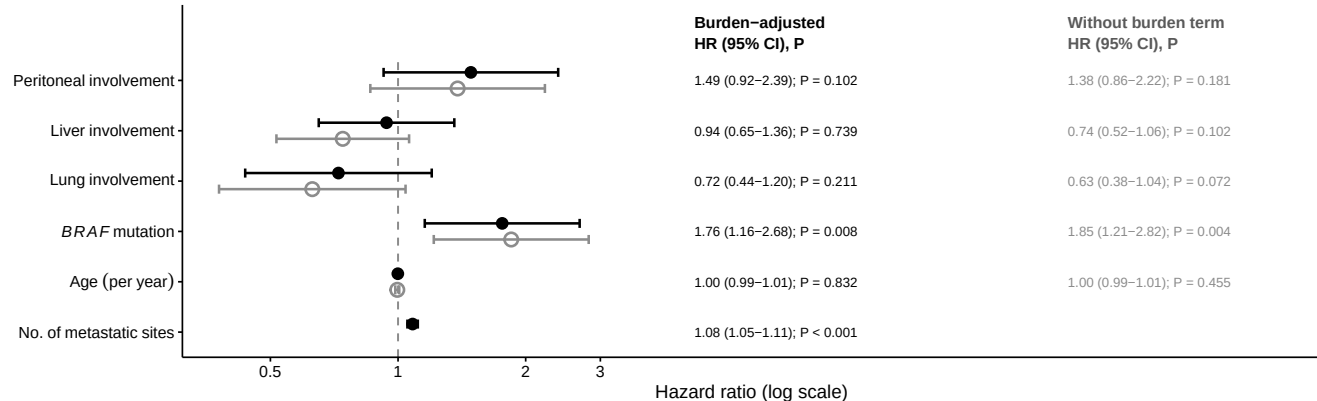

** FDR < 0.01 (BH across 9 genes). Red: significant enrichment with peritoneal involvement; blue: significant depletion; grey: not significant.

C

Overall survival, Cox proportional-hazards models

Filled black: burden-adjusted; open grey: without burden term – same subset n = 405 (226 events)

In the same subset, peritoneal involvement is not significant even without the burden term (HR = 1.38, 95% CI 0.86-2.22, P = 0.181); with burden, HR = 1.49 (0.92-2.39, P = 0.102), so the loss of significance mainly reflects subset power rather than burden confounding. Burden: HR = 1.08 per site, P < 0.001. Full-cohort model without burden term (n = 1,136): peritoneal involvement HR = 1.42 (1.05-1.92), P = 0.022.
